Background and Objectives

Following the introduction of pharmacokinetic/pharmacodynamic (PK/PD) parameters in the pre-clinical development of antibiotics, the application of PK/PD in guiding the dose for individuals has been highly encouraged. However, the findings remain controversial and vary greatly, making it difficult for prescribers to determine the appropriate PK/PD parameters for individuals in practice

Aim and objectives:

This systematic review aims to identify the PK/PD targets of antibiotics treating gram-negative infections in clinical practice, with a focus on multi-drug gram-negative infections.

Methods

This systematic review was carried out and reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines. The protocol was registered on PROSPERO (CRD42022376130). Database from Cochrane Central, Web of Science, PubMed, Embase and Scopus were searched using defined terms. Studies using PK/PD targets to determine dosing regimens of parenteral antibiotics for patients with gram-negative infections in practice were selected.

- Studies were excluded if examining the PK/PD targets of antibiotics for healthy participants, virtual patients, and gram-positive infections.
- Study bias was evaluated using the Cochrane risk of bias tool and NHLBI for case studies.

Results

A total of 41 studies investigating 21 antibiotics and two combination antibiotics involving 799 participants were selected (figure 1). The majority of eligible studies (21 articles, 51.2%) were case studies, while three (5.9%) studies were RCTs, and 17 (33.3%) were non-RCTs. The bias assessment results are shown in Figures 2, 3, and 4.

Approximately 60% of the investigated population were resistant to at least one antibiotic (Figure 5). Also, among those who used the same PK/PD parameters as suggested by EUCAST, more than 60% modified the dosing and the duration of administration to attain a higher target value (Figure 6). Cefiderocol and Meropenem were the two antibiotics most prescribed for multi-drug resistant bacteria, usually combined with other antibiotics. Extended infusion of Meropenem to at least 30 minutes per administration resulted in the achievement of 100% $fT>MIC$ or 100% $fT>4-6$ MIC instead of 40% $fT>MIC$ while the prescription of Cefiderocol followed the labelled instruction of use.

Figure 1: Numbers of antibiotics used in the included population (cases presented in the chart included non-resistant or unknown resistant cases)

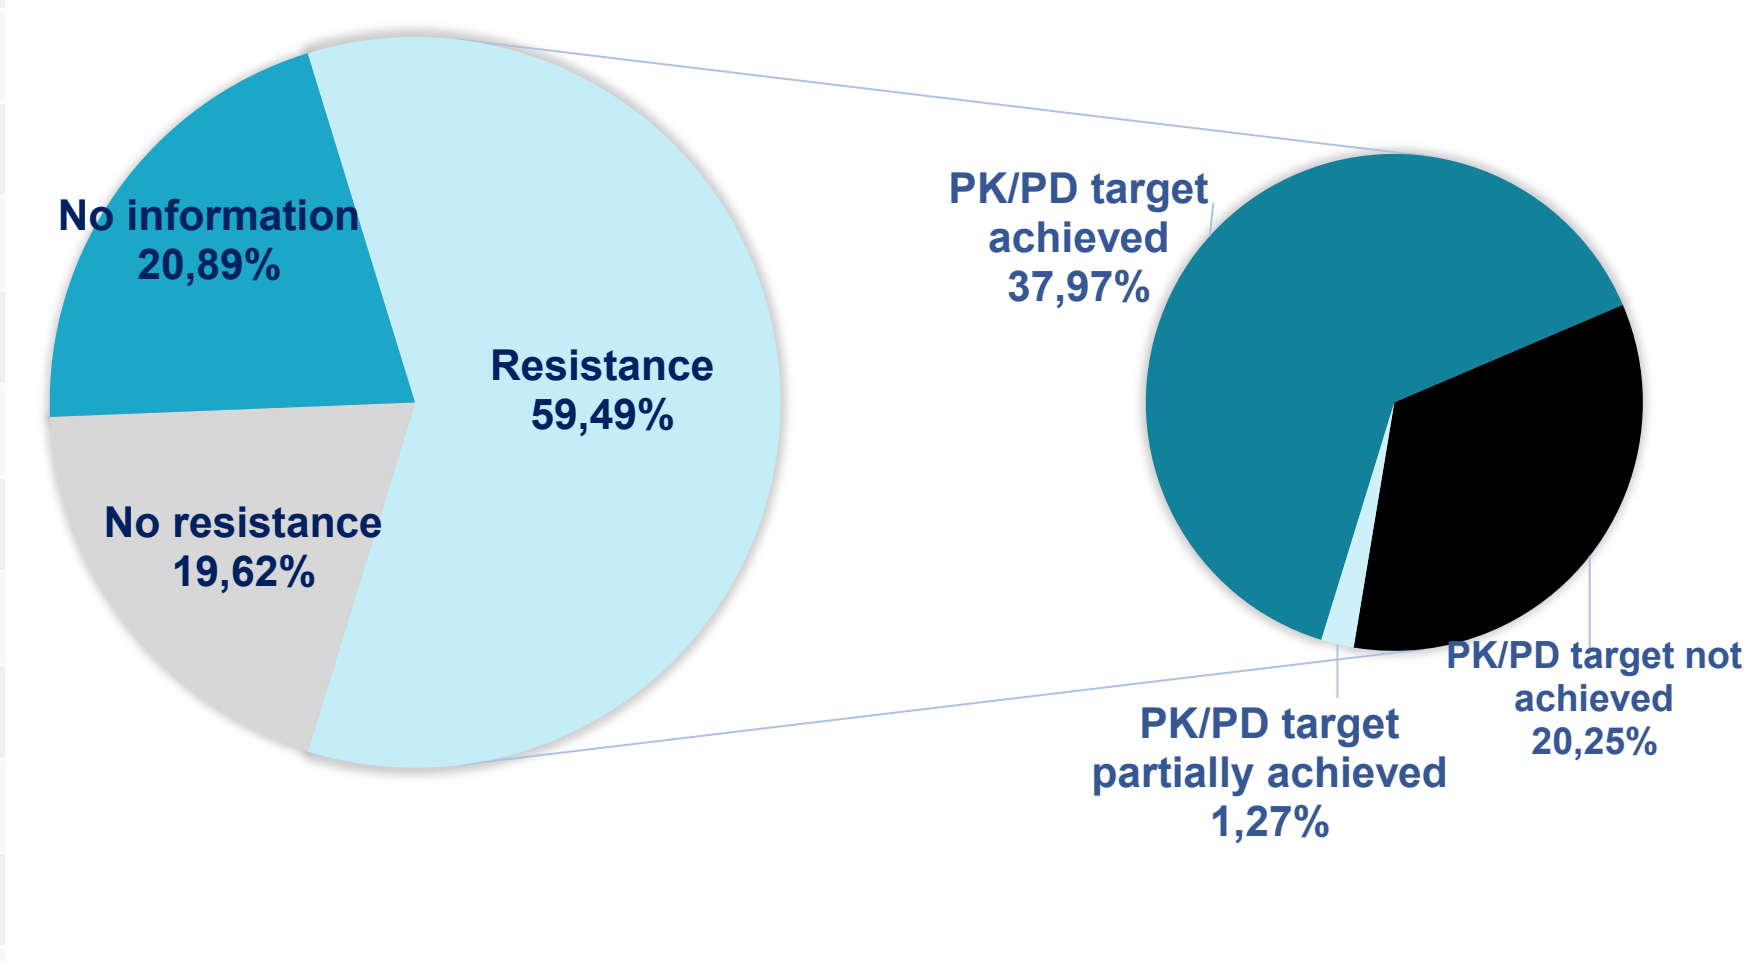

Figure 5: Percentage of bacterial resistance and the percentage that reached PK/PD targets

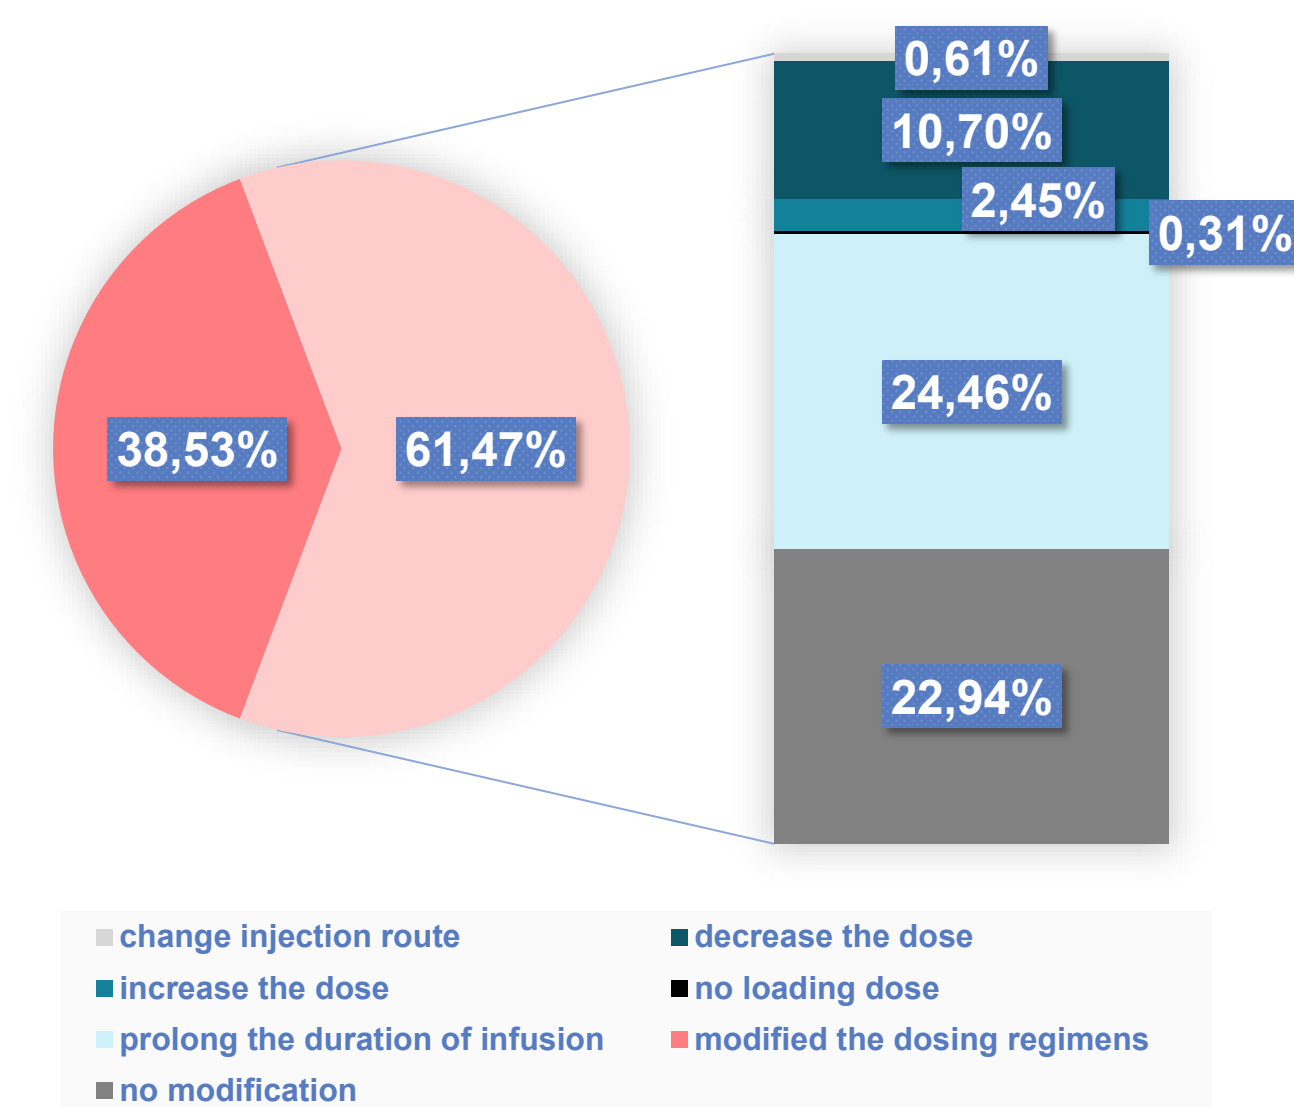

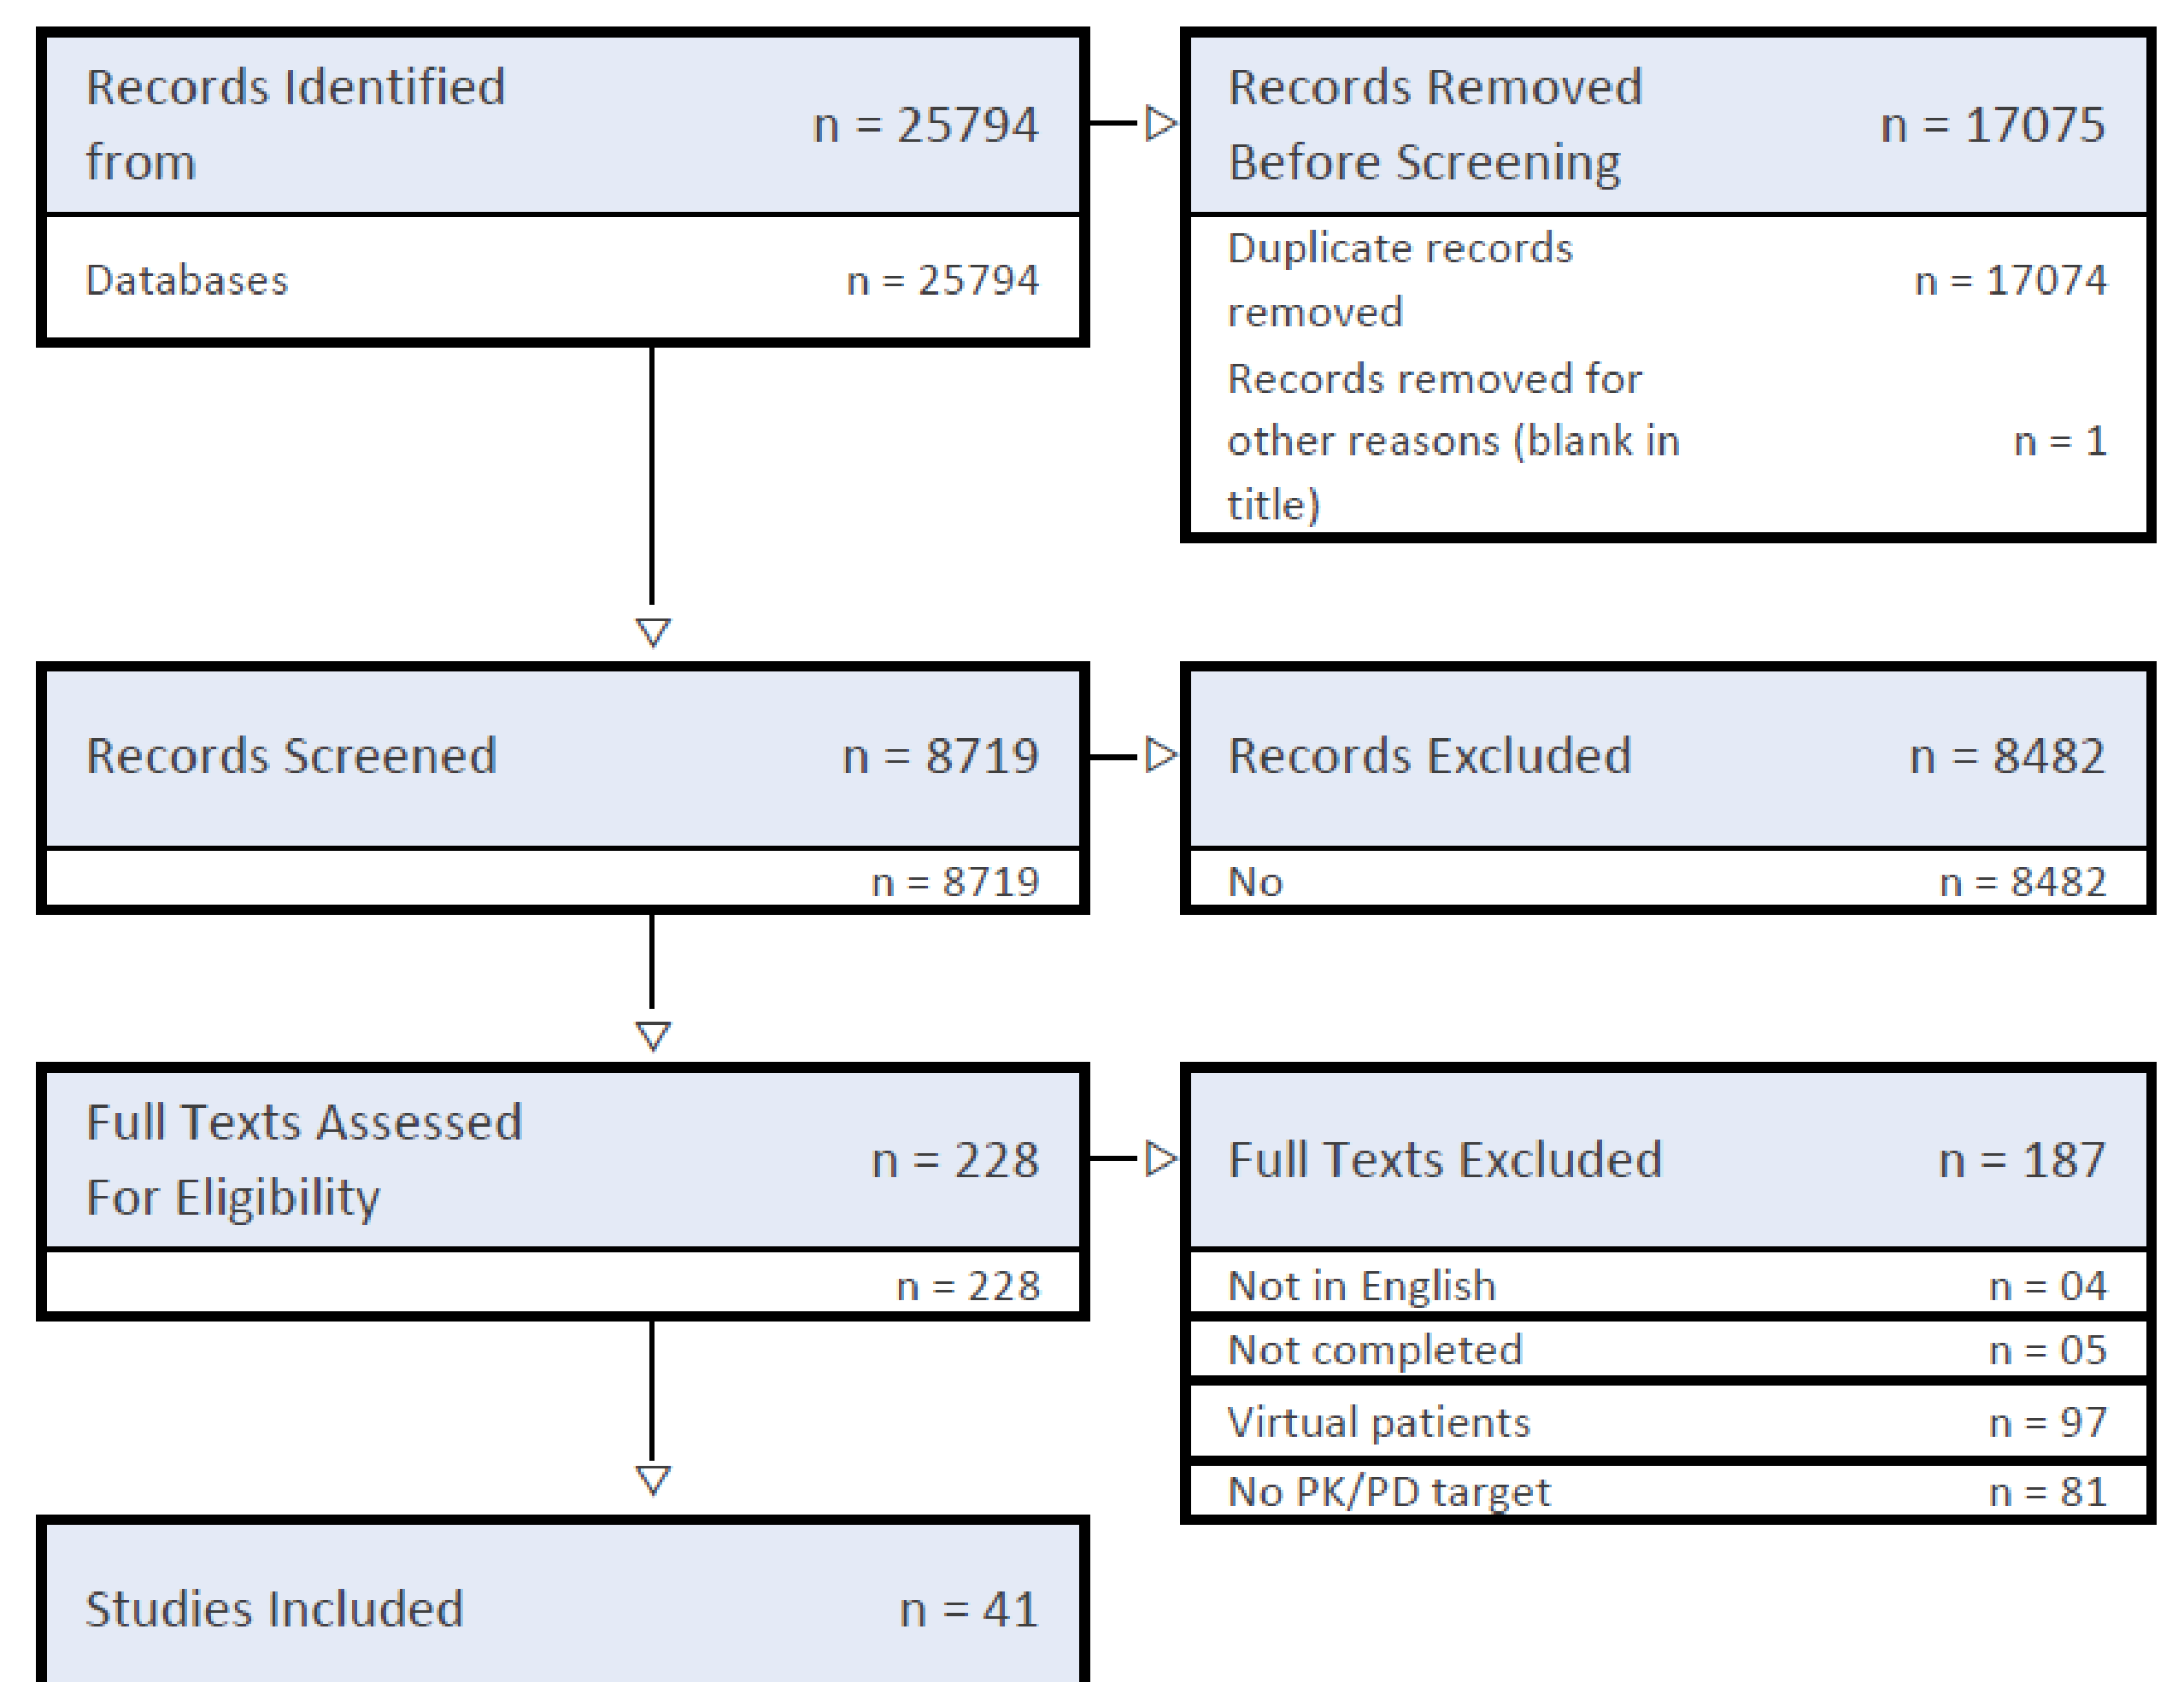

Figure 6: Percentage of cases that utilize the same PK/PD parameters as EUCAST preclinical data

IDENTIFICATION OF NEW STUDIES VIA DATABASES AND REGISTERS

Conclusion

The PK/PD target values of antibiotics treating resistant gram-negative bacteria are variable and divergent from preclinical data. A range of PK/PD targets may be more realistic in practice to optimise dosing regimens for the facilitation of clinical outcomes, and PK/PD targets should be used to inform dosing regimens. Further research with standardised patient outcomes is required.
